Escritura Científica

Maria Belén Rodríguez-Fonseca

"In science, the credit goes to the man who **convinces** the world, not to the man to whom the idea first occurs."

--Sir William Osler

"Writing is an art. But when it is writing to inform it comes close to being a science as well."

--Robert Gunning, *The Technique of Clear Writing*

¿Qué trabajo ?

- Escribir el TFM
- Escribir un informe de clase
- Escribir un TFG
- Escribir un informe de PE
- Escribir un artículo científico

A escribir se aprende escribiendo

- Práctica, práctica, práctica
- Elegir un buen modelo
- Estudiar buenos ejemplos
- **PERO...pero hay alguna técnicas y consejos**

Se te va a juzgar por lo que escribas

Además de esta charla te recomiendo:

Lee, presta atención a otros e imita

Habla de tu trabajo con otros antes de escribir

Desarrolla un hábito de “thesaurus”

Busca las palabras adecuadas que describan lo que quieres comunicar

Repeta a la audiencia que te lee. No les aburras. Empatiza

Acepta que es difícil y respeta que es importante hacerlo bien.

No vale un buen resultado. Hay que saber comunicarlo

Introducción

Antes de empezar a escribir..pregúntate

¿Qué quiero decir?

Cuando acabes de escribir..pregúntate:

¿ He transmitido lo que quería?

Lo bien que comuniques afectará a

-tu futuro

-opinión pública

-toma de decisiones

-sociedad

Un buena forma de mejorar tu escritura es tener buenos referentes

Physics and Mathematics

Check out these authors to teach yourself about the rules of matter, motion and the particles that make up the universe as we know it.

- 1 **Richard Feynman:** Nobel Prize-winning Physicist Richard Feynman was one of the best-known scientists in the world during his time, and is still widely known today for his work in quantum mechanics, particle physics and superfluidity. Besides being a whiz in the lab, Feynman helped to popularize the subject through his books and lectures, most notably in *The Feynman Lectures on Physics*.
- 2 **Michio Kaku:** Few have brought physics into popular culture like Michio Kaku. His books *Physics of the Future* and *Parallel Worlds*, among others, have helped to make him a well-known figure and cemented his role in the history of scientific writing.
- 3 **Steven Weinberg:** This Nobel Laureate in physics has written a number of books that address everything from the fundamentals of cosmology to the discovery of subatomic particles. His research has helped the field make great strides, and his work is well worth a read.
- 4 **Albert Einstein:** Famous the world over and possessing a name that's synonymous with genius, this physicist's theories helped to change the way scientists thought about time, space and bodies in motion. His publications on relativity are well worth a read for anyone, as he uses powerful examples to explain some of the more difficult concepts.
- 5 **Erwin Schrodinger:** Best known for his work in physics, which won him a Nobel Prize, Schrodinger's work covers topics from that field to the biological sciences. His most popular works include *What Is Life?* and *The Interpretation of Quantum Mechanics*.
- 6 **Ian Stewart:** A great promoter of mathematics, Ian Stewart has won awards for his books that bring math and science to a popular audience. Sci-fi fans will love his *Science of Discworld* series and math geeks will appreciate his texts like *Nature's Numbers*.
- 7 **Steven Strogatz:** This mathematician's work has been applied to diverse fields like sociology, business and epidemiology. His writings help make even the most complex topics accessible, interesting and even emotionally compelling.

How to construct a *Nature* summary paragraph

Recomendación sobre un buen abstract

Annotated example taken from *Nature* **435**, 114–118 (5 May 2005).

One or two sentences providing a **basic introduction** to the field, comprehensible to a scientist in any discipline.

Two to three sentences of **more detailed background**, comprehensible to scientists in related disciplines.

One sentence clearly stating the **general problem** being addressed by this particular study.

One sentence summarising the main result (with the words “**here we show**” or their equivalent).

Two or three sentences explaining what the **main result** reveals in direct comparison to what was thought to be the case previously, or how the main result adds to previous knowledge.

One or two sentences to put the results into a more **general context**.

Two or three sentences to provide a **broader perspective**, readily comprehensible to a scientist in any discipline, may be included in the first paragraph if the editor considers that the accessibility of the paper is significantly enhanced by their inclusion. Under these circumstances, the length of the paragraph can be up to 300 words. (The above example is 190 words without the final section, and 250 words with it).

During cell division, mitotic spindles are assembled by microtubule-based motor proteins^{1,2}. The bipolar organization of spindles is essential for proper segregation of chromosomes, and requires plus-end-directed homotetrameric motor proteins of the widely conserved kinesin-5 (Bim C) family³. Hypotheses for bipolar spindle formation include the ‘push–pull mitotic muscle’ model, in which kinesin-5 and opposing motor proteins act between overlapping microtubules^{2,4,5}. However, the precise roles of kinesin-5 during this process are unknown. Here we show that the vertebrate kinesin-5 Eg5 drives the sliding of microtubules depending on their relative orientation. We found in controlled *in vitro* assays that Eg5 has the remarkable capability of simultaneously moving at $\sim 20 \text{ nm s}^{-1}$ towards the plus-ends of each of the two microtubules it crosslinks. For anti-parallel microtubules, this results in relative sliding at $\sim 40 \text{ nm s}^{-1}$, comparable to spindle pole separation rates *in vivo*⁶. Furthermore, we found that Eg5 can tether microtubule plus-ends, suggesting an additional microtubule-binding mode for Eg5. Our results demonstrate how members of the kinesin-5 family are likely to function in mitosis, pushing apart interpolar microtubules as well as recruiting microtubules into bundles that are subsequently polarized by relative sliding. We anticipate our assay to be a starting point for more sophisticated *in vitro* models of mitotic spindles. For example, the individual and combined action of multiple mitotic motors could be tested, including minus-end-directed motors opposing Eg5 motility. Furthermore, Eg5 inhibition is a major target of anti-cancer drug development, and a well-defined and quantitative assay for motor function will be relevant for such developments.

Parte introductoria del abstract

-introducción básica

-estado del arte más específico (trabajos mas recientes)

-problema a plantear (presentas el tema)

Ejemplo:

The El Niño-Southern Oscillation (ENSO) and the variability in the Pacific subtropical highs (PSHs) have major impacts on social and ecological systems.

Several studies have proposed the boreal summer equatorial atlantic sea surface temperature variability as main predictor of ENSO in recent decades.

Nevertheless the mechanisms acting on this relationship are not clear so far.

Parte media del abstract- Dos aproximaciones

...Here we present an Atlantic capacitor effect mechanism to suggest that the Atlantic is a key pacemaker of the biennial variability in the Pacific including that in ENSO and the PSHs during recent decades. The 'charging' (that is, ENSO imprinting the North Tropical Atlantic (NTA) sea surface temperature (SST) via an atmospheric bridge mechanism) and 'discharging' (that is, the NTA SST triggering the following ENSO via a subtropical teleconnection mechanism) processes alternate, generating the biennial rhythmic changes in the Pacific.

Here we present an Atlantic capacitor effect mechanism to suggest that the Atlantic is a key pacemaker of the biennial variability in the Pacific including that in ENSO and the PSHs during recent decades. By analysing the two-way regression maps of North Tropical Atlantic on the Pacific, a charging-'discharging' processes is found as the main mechanism that generates the biennial rhythmic changes in the Pacific.

Descriptivo

nature
How to construct a Nature summary paragraph

Annotated example taken from Nature 435, 114-118 (5 May 2009).

The diagram illustrates the structure of a Nature summary paragraph with color-coded boxes and arrows pointing to specific parts of the text:

- Red box:** One or two sentences providing a basic introduction to the field, comprehensible to a scientist in any discipline.
- Orange box:** Two to three sentences of more detailed background, comprehensible to scientists in related disciplines.
- Yellow box:** One sentence clearly stating the general problem being addressed by this particular study.
- Green box:** One sentence summarizing the main result (with the words 'here we show' or their equivalent).
- Blue box:** One or two sentences explaining what the main result reveals in direct comparison to what was thought to be the case previously, or how the main result adds to previous knowledge.
- Light green box:** One or two sentences to put the results into a more general context.
- Light orange box:** Two or three sentences to provide a broader perspective. Ideally, comprehensible to a scientist in any discipline, may be included in the first paragraph if the editor considers that the accessibility of the paper is significantly enhanced by their inclusion. Under these circumstances, the length of the paragraph can be up to 200 words. (The above example is 190 words without the final section, and 250 words with it).

The text of the paragraph is as follows:

During cell division, mitotic spindles are assembled by microtubule-based motor proteins^{1,2}. The bipolar organization of spindles is essential for proper segregation of chromosomes, and requires plus-end-directed homodimeric motor proteins of the widely conserved kinesin-5 (BimC) family³. Hypotheses for bipolar spindle formation include the 'push-pull mitotic motor' model, in which kinesin-5 and opposing motor protein act between overlapping microtubules^{4,5}. However, the precise roles of kinesin-5 during this process are unknown. Here we show that the vertebrate kinesin-5 Eg5 drives the sliding of microtubules depending on their relative orientation. We found in controlled *in vitro* assays that Eg5 has the remarkable capability of simultaneously moving at ~20 nm s⁻¹ towards the plus-ends of each of the two microtubules it crosslinks. For anti-parallel microtubules, this results in relative sliding at ~40 nm s⁻¹, comparable to spindle pole separation rates *in vivo*. Furthermore, we found that Eg5 can tether microtubule plus-ends, suggesting an additional microtubule-binding mode for Eg5. Our results demonstrate how members of the kinesin-5 family are likely to function in mitosis, pushing apart interpolar microtubules as well as recruiting microtubules into bundles that are subsequently polarized by relative sliding. We anticipate our assay to be a starting point for more sophisticated *in vitro* models of mitotic spindles. For example, the individual and combined action of multiple mitotic motors could be tested, including minus-end-directed motors opposing Eg5 motility. Furthermore, Eg5 inhibition is a major target of anti-cancer drug development, and a well-defined and quantitative assay for motor function will be relevant for such developments.

For example, the individual and combined action of multiple mitotic motors could be tested, including minus-end-directed motors opposing Eg5 motility. Furthermore, Eg5 inhibition is a major target of anti-cancer drug development, and a well-defined and quantitative assay for motor function will be relevant for such developments.

Esta parte saca la conclusión general y su repercusión

Un buen abstract organiza el documento:

no empezar a escribir hasta tener una clara idea

Organización

Desarrollar en párrafos las frases de la intro del abstract

intro básica: presenta el tema general

-estado del arte más específico: focaliza más

-problema

La introducción define el objetivo y las limitaciones del estudio

La lluvia ocurre en una estación determinada

Solo hay unos pocos trabajos

tema

**Estudio de la precipitación
Anómala en Brasil**

Que estudios se han hecho

-Como es la precipitación anomala
-a que se debe
-cuando ocurre

general

Los estudios disponibles abarcan pocos años

Ahora existen mejores datos

limitaciones

Al final de una buena introducción se le indica al lector **POR QUE** es importante el trabajo

This paper presents a design for a platinum catalytic igniter in hydrogen-air mixtures. This igniter has application in nuclear reactors. One danger at a nuclear reactor is a loss-of-coolant accident. Such an accident can produce large quantities of hydrogen gas when hot water and steam react with zirconium fuel rods. In a serious accident, the evolution of hydrogen may be so rapid that it produces an explosive hydrogen-air mixture in the reactor containment building. This mixture could breach the containment walls and allow radiation to escape.

Our method to eliminate this danger is to intentionally ignite the hydrogen-air mixture at concentrations below those for which any serious damage might result.

Resumen

¿Cómo hacer una buena introducción?

- Extendiendo las 3-4 primeras frases del abstract en 3-4 párrafos
- Referenciando adecuadamente el trabajo de otros
- Remarcando la necesidad del estudio
- Escribiendo manteniendo el **suspense (no cuentes el resultado)**
- Tiempo verbal: pasado para referencias, presente para el trabajo actual y su necesidad. Ser constante con los tiempos verbales.
- La introducción ha de llevar figuras ilustrativas

Los objetivos se pueden poner al final de la introducción

Organización

Muchas revistas siguen una forma común de organización IMRaD

Introducción, Materiales y Métodos, Resultados y Discusión

Introducción

Materiales y Metodos

Resultados

Discusión

Materiales y Métodos

- Haz referencia a las herramientas (datos, medidas de laboratorio, experimentos) y métodos de análisis empleados.
- La metodología es normalmente fácil de escribir porque es descriptiva.
- Ordena la metodología de la misma forma en la que presentarías los resultados

Escribe
materiales y
métodos junto
con los
resultados

Secciones Intermedias: Resultados

Escribe
materiales y
métodos junto
con los
resultados

Elige una estrategia

Haz secciones y subsecciones

Heading

Subheading

- Influencia Pacífica

- Papel de los eddies tropicales
- Papel de los eddies extratropicales

Resultados

Ayuda: escribe
introducción tras
los resultados
para organizar
tus ideas

- Van acompañados de figuras y tablas
- son descriptivos pero no interpretativos

“Ejemplo1: These data show that something is higher/faster/larger than something else ($p < 0.001$)”

“Ejemplo 2: Al aumentar x aumenta y”

- Describir no es volver a poner el pie de figura, la figura se menciona porque apoya la descripción
- Un error normal es añadir discusión e interpretación a esta sección

Esto no deja espacio para la sección de discusión

Importancia de Figuras y Tablas en Resultados

- Los conceptos nuevos fundamentales han de ir acompañados de figuras y/o tablas.
- los resultados han de apoyarse por figuras y tablas
- Las principales figuras de tu estudio van en la parte intermedia
- La descripción de las figuras y tablas va en el pie de figura y NO en el texto
- Describir las figuras en el texto resta agilidad a la lectura
- Referenciar en el pie de figura la fuente en el caso de usar figuras ajenas.

¿Como escribir?

The Elements of Style, William Strunk Jr. (disponible en: <http://www.bartleby.com/141/>):

“La escritura ha de ser concisa. Una frase no puede contener palabras innecesarias, un párrafo no puede contener frases innecesarias. Esto no obliga a que el escritor escriba TODAS las frases cortas o que evite los detalles, sino que tenga en cuenta que todo cuenta.”

William Zinsser in *On Writing Well*, 1976 (no la traduzco por su interés)

The secret of good writing is to strip every sentence to its cleanest components. Every word that serves no function, every long word that could be a short word, every adverb that carries the same meaning that's already in the verb, every passive construction that leaves the reader unsure of who is doing what—these are the thousand and one adulterants that weaken the strength of a sentence. And they usually occur in proportion to the education and rank.”

Texto

Usa frases cortas con conceptos simples,
Nunca escribas una frase con muchos conceptos.
Evita la subordinadas.
Preocúpate si tu frase ocupa 3 líneas.
Usa párrafos pequeños.
Evita los paréntesis para matizar.
Usa una buena gramática y puntuacion.
Si dudas, ve a lo fácil y simple.

CONSEJO: lee en alto lo que has escrito. Si no fluye, algo falla. Prueba a leer trozos cortos en lugar de largas secciones

El primer borrador que sea un resumen de todo

Importante: lo importante con el tiempo verbal es la consistencia

Tiempo verbal

Una buena forma de separar lo que uno ha hecho de lo que otros han realizado es mezclar los tiempos verbales, usando cada uno para una cosa y no mezclando en una misma cosa

Esto es normal en la parte de discusión

Ejemplo:

The protein **was** non-functional after modification of the terminal residue. This result **is** consistent with those from other groups (references) and **indicates**....

Discusión

Un buen final, Analizas los resultados y das perspectivas futuras

Conclusiones

Análisis de Resultados

Analizar los resultados de una forma global

Perspectivas Futuras

Tras la introducción se suele escribir la discusión, que interpreta los resultados y los coloca en el contexto de la literatura disponible.

Opciones:

***Hacer recomendaciones
Discutir trabajo futuro
Repetir las limitaciones***

Uso de Apéndices para proporcionar mas informacion a otras audiencias

Appendice A Concern About the Greenhouse Effect

For almost a hundred years, experts have been concerned with the increasing concentrations of gases such as carbon dioxide, methane, and nitrogen oxides in the earth's lower atmosphere. These gases are natural by-products of combustion. Figure A-1 illustrates the correlation between global temperature and carbon dioxide concentrations...

Uso de apéndices para proporcionar información tangencias a lectores primarios

Apendice B **Project Stormfury**

In 1961, the United States Weather Bureau and the Department of Defense (Navy) began a project to reduce the strength of hurricanes. The project, called Project Stormfury, uses cloud seeding, a process used to produce rainfall and reduce hail in thunderstorms. In Project Stormfury, silver iodide crystals, similar in structure to ice, are dispersed by airplanes in the upper reaches of cloud formations just outside the hurricane's eye where the winds are highest. Initial results showed that wind speeds decreased between 15–30% after seedings...

Uso de glosario de términos para definir términos no familiares

Glosario

burst point: the exact point in space where an atomic bomb is detonated.

clear visibility: a viewing range of twenty miles.

fallout: the descent to the Earth's surface of radioactive particles from a cloud contaminated with the fission products of a nuclear explosion.

hypocenter: the point on the earth's surface directly below the burst point; also called ground zero.

Uso de lista de Acrónimos

ECMWF: European Center for Medium Range Weather Forecast

GHGs: Green House Gases

GW: Global Warming

SST: Sea surface temperature

Title

Abstract

Introduction

Methodology

Results

Discussion

References

Figure/Tables legends

En un artículo científico lo normal es una estructura de este estilo

- **Formato:** Cómo escribir

Procesadores

- LaTeX: Mac, Linux, Windows

(<http://nokyotsu.com/latex/osx.html>)

(existen editores o puedes escribir directamente visualizando el código fuente)

Word (existen plantillas para escribir trabajos)

<https://templates.office.com/en-us/templates-for-Word>

- Open Office (software libre)
- Libre Office (software libre...con más futuro!!)

Las revistas científicas ofrecen sus plantillas

“Instructions to authors”

- Muchas revistas o informes dan instrucciones
- En general:

Lee las instrucciones generales a cumplir antes de escribir

Todas las revistas tienen un estilo

Ejemplo:

The BMJ insists all papers are written in first person I demonstrated that....

Las revistas MAS CIENTÍFICAS tienden a requerir la tercera persona o impersonal

These data demonstrate that....

Se ha demostrado como los datos...

Figuras

-Las figuras se numeran

Se nombran en el texto como **Figura x** .

Cuando van entre paréntesis, muchas veces van abreviadas

Ejemplo:

Figure 1 shows an increase of temperature with height

An increase of temperature with height is observed (Fig.1)

-Con un número Figure 1, Fig.1

-Con 2: uno relativo a la sección y otro a la numeración dentro de la sección. Figure 3.4 , Fig 3.4

Pies de figura (Figure captions)

Descripción de la figura

Descripción de la variable que se representa

Unidades de la variable

Asociación con colores o isolíneas

Fuente en caso de figura ajena

El pie de figura ha de contener la información necesaria para su autonomía

-Caso de dos figuras iguales pero para diferentes variables

Indicar que es igual y matizar la diferencia: “Idem que en Figura x pero para la temperatura”

Figure 1 | Correlations between the ENSO and NTA SST indices.

(a) The 21-year sliding correlation coefficients (for example, correlation coefficient in 2002 representing 1992–2012) between preceding boreal winter (DJF) Niño3.4 and spring (MAM) NTA SST during 1948–2016.

(b) Same as **a** but for MAM NTA SST and subsequent DJF Niño3.4.

Following ref. 20, the impact of the previous winter ENSO has been excluded in **b** by removing the linear regression with respect to the Niño3.4 index during the previous DJF season. The linear trend has been removed within each sliding window for both indices before calculating the sliding correlation coefficients. The red dots represent correlations that are significant at the 95% confidence level.

LOS PIES DE FIGURA TIENEN QUE SER MUY PRECISOS Y EXPLICAR TODO LO QUE SE VE

Figure 3 | Regression with respect to spring NTA SSTA. (a–c) Regressions of SSTAs (shading) and 850-hPa winds (vector) with respect to the MAM NTA SSTA during P1 for MAM (a), JJA (b) and DJF (c) seasons. (d–f) Same as a–c but for during P2 for MAM (d), JJA (e) and DJF (f) seasons. The impact of the previous winter ENSO has been excluded by removing the linear regression with respect to the Niño3.4 index during the previous DJF season. Only the values at the 90% confidence level or higher are shown.

¿cómo ha de ser una buena figura?

Tiene que ilustrar el concepto que acompaña al párrafo que la describe.

Puede estar formada por diferentes tipos de gráficas, pero en asociación. Simple en colores y formas. No muy recargadas

Todo lo que se muestra se tiene que poder ver.

Imprímela primero o ponla en el tamaño del documento final en la pantalla para comprobar si se ven.

(cuidado con etiquetas de los ejes, ticks, valores en los contornos en mapas de isolineas, etc..)

¿cómo resumir en 5 figuras mi trabajo?

-No se muestran TODAS las figuras que uno ha realizado sino el resumen de las mismas

Es bueno hacer figuras resumen

Ejemplo:

En lugar de poner un conjunto de mapas donde lo único que cambia es la localización de un máximo, haz una gráfica donde se ve el valor del máximo en el eje de ordenadas y la localización de dicho máximo en el eje x.

-Cada párrafo va asociado a la descripción de una figura. La figura ha de representar un resultado. Intenta agrupar tus resultados en 3 o 4 conceptos y, para cada uno, busca una figura.

Tablas

-Las tablas se numeran

Se nombran en el texto con un sólo número (Tabla 1)
O Con 2 números: uno relativo a la sección y otro a la numeración dentro de la sección (Tabla 2.1).

-Pie de tabla

Descripción de la tabla por filas y columnas

Descripción de la variable que se representa

Unidades de la variable

Significado de subrayados o alteraciones

Procedencia en caso de tabla ajena

El pie de tabla ha de contener la información necesaria para su autonomía

-Caso de dos tablas iguales con una ligera diferencia

Indicar que es igual y matizar la diferencia: “Idem que en Tabla x pero para ...”

sphere (TOA). Table 1 shows the model names, modeling centers, and whether the AMIP simulations are available. Further information on individual models is available online (at <http://www-pcmdi.llnl.gov/>; Taylor et al. 2012). Here, we only use one ensemble member (“r1i1p1”) run for each model.

TABLE 1. A list of the 18 CMIP5 climate models used in this study and the labels to denote them in the figures and text.

Model name (label)	Model expanded name	Model group (or center)	Including AMIP simulations?

HIGH FREESTREAM TURBULENCE EFFECTS ON ENDWALL HEAT TRANSFER FOR A GAS TURBINE STATOR VANE

R.W. Radomsky* and K.A. Thole

Mechanical Engineering Department
Virginia Polytechnic Institute and State University
Blacksburg, Virginia 24060

ABSTRACT

High freestream turbulence along a gas turbine airfoil and strong secondary flows along the endwall have both been reported to significantly increase convective heat transfer. This study superimposes high freestream turbulence on the naturally occurring secondary flow vortices to determine the effects on the flowfield and the endwall convective heat transfer. Measured flowfield and heat transfer data were compared between low freestream turbulence levels (0.6%) and combustor simulated turbulence levels (19.5%) that were generated using an active grid. These experiments were conducted using a scaled-up, first stage stator vane geometry. Infrared thermography was used to measure surface temperatures on a constant heat flux plate placed on the endwall surface. Laser Doppler velocimetry (LDV) measurements were performed of all three components of the mean and fluctuating velocities of the leading edge horseshoe vortex. The results indicate that the mean flowfields for the leading edge horseshoe vortex were similar between the low and high freestream turbulence cases. High turbulence levels in the leading edge-endwall junction were attributed to a vortex meandering for both the low and high freestream turbulence cases. While, in general, the high freestream turbulence increased the endwall heat transfer, low augmentations were found to coincide with the regions having the most intense vortex motions.

INTRODUCTION

Along a turbine airfoil surface, elevated convective heat transfer coefficients occur as a result of high turbulence intensities along a gas turbine engine. The platform of an airfoil (endwall), a critical surface where durability can be an issue, also has high convective heat transfer levels with a complex footprint. The complexity occurs from the secondary flows that develop in the form of vortices that envelop the platform surface. Both of these effects, high freestream turbulence effects on airfoil heat transfer and secondary flow effects on endwall heat transfer, have been discussed in the literature. What is missing from the literature is the combined effects of combustor level freestream turbulence and secondary flows on endwall heat transfer.

Turbulence measurements taken at the exit of a variety of gas turbine combustors have shown that the levels can range between 8% and 40% (Goldstein, et al., 1983; Krummen and McGurk, 1989; and Gossel, et al., 1993) with some indication that the integral length scale scales with the diameter of the dilution holes in the combustor (Moss, 1992). As these high levels progress through the downstream turbine vane passage, there is a production of turbulence resulting in high turbulent kinetic energy levels at the exit of the passage (Radomsky and Thole, 1999). The effect that these high turbulence levels has on the airfoil itself is to significantly increase the heat transfer along the leading edge and pressure side surfaces as well as move the transition location forward on the suction side surface.

The secondary flows previously mentioned take the form of a leading edge horseshoe vortex. This vortex splits into one leg that wraps around the suction surface and another leg that wraps around the pressure surface with the latter ultimately forming a passage vortex. As the flow progresses downstream, the flow is dominated by the passage vortex. Grainger and Russell (1984) identified, through flow visualization and surface heat transfer, that high convective heat transfer coefficients coincided with the most intense vortex action. Kang and Thole (1999) showed through flow field and heat transfer measurements that the peak heat transfer coincided with the downward legs of both the horseshoe vortex and passage vortex. The downward leg of these vortices brings high speed freestream fluid towards the endwall and drives the boundary layer to ultimately increase the local heat transfer coefficients. As seen in several past endwall heat transfer studies (Chapman, et al., 1980; and Blythe and Russell, 1990; Kang, et al., 1999) the peak heat transfer on the passage endwall occurs from the pressure side of the airfoil to the suction side of the adjacent airfoil as the passage vortex moves in this direction.

Although there have been a number of studies documenting high freestream turbulence effects on airfoil heat transfer and there have been a number of endwall flowfield and heat transfer studies, there are no studies documenting endwall heat transfer at combustor level freestream turbulence. The work presented in this paper investigates the effect that high turbulence has on endwall heat transfer. In particular, one of the regions having the highest heat transfer is the leading edge-endwall junction. Three-dimensional flowfield mea-

ator, described in detail by Radomsky (1999), is shown in Figure 1. The test section contains the high turbulence levels. The low square bars with jets injecting into the upstream and downstream directions. The jet holes having a diameter of 1.5 mm. These hollow bars were installed 88 mm upstream of the stagnation point. A jet that supplied each of the bars. The jet grid was 19.5% measured at 0.33 mm location. The integral length scale 0.12 and was uniform across the span of the inlet flow quality will be given

in a plane at the endwall-vane junction location that intersects the stagnation point chosen to compare with that provided at low turbulence conditions. The optic LDV system used in this study conjunction with a TSI model 9200 data was processed using TSI model software using TSI's PIND software. U , V , and W were measured with a two-tier (LDV) positioned in two different planes with a beam expander was used on the measurements of the streamwise

(U) and pitchwise (W) components through the top endwall; and the streamwise (U) and spanwise (V) components through the sidewall. Coincident measurements were made through the sidewall to quantify the Reynolds shear stress, τ_{xy} . The probe volume length and diameter for the 750 mm lens with the beam expander were 0.85 mm and 72 microns. The data were corrected for velocity bias effects by applying residence time weighting.

Endwall Heat Transfer Measurements

The heat transfer results for the high freestream turbulence conditions were measured in the same facility as for the low freestream turbulence conditions (Kang, et al., 1999). These measurements were obtained with a constant heat flux plate placed on the bottom endwall, as indicated by the cross-hatched area in Figure 1, surrounding the Styrofoam stator vane. The constant heat flux plate consisted of a 50 micron thick copper layer on top of a 75 micron thick kapton layer in which 25 micron thick insulating elements were embedded in a serpentine pattern. This heater was placed onto a 1.9 cm thick wooden surface using double-sided tape. Just below the wood was a 2.54 cm thick R-5 extruded Styrofoam board. The total heating area for the plate was 0.540 m² and the input power was adjusted to give a heat flux of 980 W/m². The lateral conduction was estimated to be less than 1% within the averaging spot size for the infrared camera. The top surface of the heater plate was painted black giving an emissivity of 0.94.

Surface temperature data was acquired using a calibrated infrared camera (Inframetrics Model 700). The camera was calibrated in situ using type E ribbon thermocouples that were painted black and placed on the heated surface. The calibration procedure was performed to obtain the correct plate emissivity and background temperature and insure a linear relationship between the infrared camera measurements and the thermocouple reading over the required operating temperature range. To perform these measurements, the top endwall was replaced with a plate having 13 viewing ports in which an 11.43 cm diameter crystal fluoride window or, when not making measurements from that port, a lens insert could be placed. Each endwall temperature resulted from an average of 16 images and, based on an uncertainty analysis, it was determined that five of these 16 averaged images were enough to get a good average. Small positioning crosses were placed on the endwall to identify where each of the 13 images were relative to the turbine vane. An in-house processing routine allowed the 13 images to be assembled into one complete endwall temperature distribution. The infrared camera performed a spatial averaging over 0.37 cm and operated at its maximum viewing area of 21.5 cm by 16 cm represented by 255 by 206 pixels.

The input heat flux was corrected for radiation losses, which amounted to between 7-23 % of the input power, and conduction losses, which amounted to 1.7-3.5 % of the input power. No correction was necessary regarding heat losses from conduction to the turbine vane itself because the vane was constructed using Styrofoam. Using the measured temperatures and the remaining convective heat flux, the heat transfer coefficients were computed and reported as Stanton numbers.

UNCERTAINTY ESTIMATES

The partial derivatives and sequential perturbation methods, described by Moffat (1988), were used to estimate the uncertainties of the measured values. Uncertainties were calculated based on a 95% confidence interval. For each velocity component 15,000 data points were used to compute the mean and turbulence quantities whereas when coincident data was acquired 20,000 data points were acquired. The estimate of bias and precision uncertainties for the mean velocities were 1% while the precision of the raw velocities was 2.1% for u_{rms} , 1.7% for the v_{rms} and

Simulations using probabilistic distributions often represent a more realistic model in a number of situations, since producing and assembling parts to exactly the same dimension every time is not possible. An excellent example of statistical variation is found in gas turbine manufacturing where no manufactured part or clearance is ever at the *exact* nominal dimensions specified in the design. There is always a tolerance around the nominal value that results from the variation that is inherent to any manufacturing process. For a number of years, a wide range of industries have been using statistical models to control the quality of their product. More recently, industries have begun to formalize their statistical quality control, and have been putting forth a great deal of time and money to educate employees on the use of statistical methods. "Six Sigma" is an example of this formalization of statistical control, and is now in the forefront of many corporate training agendas.

Also presented with this work are methods to determine which level of reliability is most cost effective for an engine manufacturer. The cost-tolerance models used in this research are simple and intended to illustrate qualitative trends only. Lastly, the analysis methods presented in this work will be shown to be the foundation for future work that involves predicting the performance reliability of engines over time.

1.2 Approach

The approach used to conduct this research was modular in nature, with each successive step building upon the previous step. As such, this document is organized in a manner to walk the reader through each step in detail. This section gives a brief overview of each step that will later be discussed in more detail.

The first stage in being able to predict the performance reliability of an engine is simply being able to predict the performance of the engine with single point nominal inputs. Performance prediction models are common in aero-engine manufacturing industries and often provide very accurate predictions of engine performance. For variability-analysis methods such as those presented in this research, accurate

High freestream turbulence along a gas turbine airfoil and strong secondary flows along the endwall have both been reported to significantly increase convective heat transfer. This study superimposes high freestream turbulence on the naturally occurring secondary flow vortices to determine the effects on the flowfield and the endwall convective heat transfer. Measured flowfield and heat transfer data were compared between low freestream turbulence levels (0.6%) and combustor simulated turbulence levels (19.5%) that were generated using an active grid. These experiments were conducted using a scaled-up, first stage stator vane geometry. Infrared thermography was used to measure surface temperatures on a constant heat flux plate placed on the endwall surface. Laser Doppler velocimetry (LDV) measurements were performed of all three components of the mean and fluctuating velocities of the leading edge horseshoe vortex. The results indicate that the mean flowfields for the leading edge horseshoe vortex were similar between the low and high freestream turbulence cases. High turbulence levels in the leading edge-endwall junction were attributed to a vortex meandering for both the low and high freestream turbulence cases. While, in general, the high freestream turbulence increased the endwall heat transfer, low augmentations were found to coincide with the regions having the most intense vortex motions.

INTRODUCTION

Along a turbine airfoil surface, elevated convective heat transfer coefficients occur as a result of high turbulence and secondary flows in a gas turbine engine. The platform of an airfoil (endwall), a critical surface where durability can be an issue, also has high convective heat transfer levels with a complex footprint. The complexity occurs from the secondary flows that develop in the form of vortices that envelop the platform surface. Both of these effects, high freestream turbulence effects on airfoil heat transfer and secondary flow effects on endwall heat transfer, have been discussed in the literature. What is missing from the literature is the combined effects of combustor level freestream turbulence and secondary flows on endwall heat transfer.

Turbulence measurements taken at the exit of a variety of gas turbine combustors have shown that the levels can range between 8% and 40% (Goldstein, et al., 1983; Kriestman and McIntire, 1989; and Ghobad, et al., 1993) with some indication that the integral length scale scales with the diameter of the dilution holes in the combustor (Moss, 1992). As these high levels progress through the downstream turbine vane passage, there is a production of turbulence resulting in high turbulent kinetic energy levels at the exit of the passage (Radomsky and Thole, 1999). The effect that these high turbulence levels has on the airfoil itself is to significantly increase the heat transfer along the leading edge and pressure side surfaces as well as move the transition location forward on the suction side surface.

The secondary flows previously mentioned take the form of a leading edge horseshoe vortex. This vortex splits into one leg that wraps around the suction surface and another leg that wraps around the pressure surface with the latter ultimately forming a passage vortex. As the flow progresses downstream, the flow is dominated by the passage vortex. Grainger and Baswell (1984) identified, through flow visualization and surface heat transfer, that high convective heat transfer coefficients coincided with the most intense vortex action. Kang and Thole (1999) showed through flow field and heat transfer measurements that the peak heat transfer coincided with the downstream legs of both the horseshoe vortex and passage vortex. The downstream leg of these vortices brings high speed freestream fluid towards the endwall and drives the boundary layer to ultimately increase the local heat transfer coefficients. As seen in several past endwall heat transfer studies (Chapman, et al., 1980; and Boyle and Baswell, 1990; Kang, et al., 1999) the peak heat transfer on the passage endwall occurs from the pressure side of the airfoil to the suction side of the adjacent airfoil as the passage vortex moves in this direction.

Although there have been a number of studies documenting high freestream turbulence effects on airfoil heat transfer and there have been a number of endwall flowfield and heat transfer studies, there are no studies documenting endwall heat transfer at combustor level freestream turbulence. The work presented in this paper investigates the effect that high turbulence has on endwall heat transfer. In particular, one of the regions having the highest heat transfer is the leading edge-endwall junction. Three-dimensional flowfield mea-

Test section containing the

ator, described in detail by Radomsky (1999), was used to generate the high turbulence levels. The low speed air was injected into the upstream duct through two sets of slots and downstream ducts. The air holes having a diameter of 1.5 mm. These hollow bars were installed 88 mm upstream of the stator position. A total of 100 slots were supplied each of the bars. The air flow rate was 19.5% measured at 0.33 bar location. The integral length scale 0.12 m and was uniform across the span of the inlet flow quality will be given

in a plane at the endwall-vane junction location that intersects the stagnation line chosen to compare with that provided in low turbulence conditions. The optic LDV system used in this study conjunction with a TSI model 9200 laser data processing using TSI model 9200 software. The U, V, and W were measured with a two-color LDV positioned in two different planes with a beam expander was used to take measurements of the streamwise

(U) and pitchwise (P) components through the top endwall; and the streamwise (U) and spanwise (W) components through the sidewall. Coincident measurements were made through the sidewall to quantify the Reynolds shear stress, $u'v'$. The probe volume length and diameter for the 750 mm lens with the beam expander were 0.85 mm and 72 microns. The data were corrected for velocity bias effects by applying residence time weighting.

Endwall Heat Transfer Measurements

The heat transfer results for the high freestream turbulence conditions were measured in the same facility as for the low freestream turbulence conditions (Kang, et al., 1999). These measurements were obtained with a constant heat flux plate placed on the bottom endwall, as indicated by the cross-hatched area in Figure 1, surrounding the Styrofoam stator vane. The constant heat flux plate consisted of a 50 micron thick copper layer on top of a 75 micron thick kapton layer in which 25 micron thick insulating elements were embedded in a serpentine pattern. This heater was placed onto a 1.9 cm thick wooden surface using double-sided tape. Just below the wood was a 2.54 cm thick R-5 extruded Styrofoam board. The total heating area for the plate was 0.549 m² and the input power was adjusted to give a heat flux of 980 W/m². The lateral conduction was estimated to be less than 1% within the averaging spot size for the infrared camera. The top surface of the heater plate was painted black giving an emissivity of 0.94.

Surface temperature data was acquired using a calibrated infrared camera (Inframetrics Model 700). The camera was calibrated in situ using type E ribbon thermocouples that were painted black and placed on the heated surface. The calibration procedure was performed to obtain the correct plate emissivity and background temperature and insure a linear relationship between the infrared camera measurements and the thermocouple reading over the required operating temperature range. To perform these measurements, the top endwall was replaced with a plate having 13 viewing ports in which an 11.43 cm diameter crystal fluoride window or, when not making measurements from that port, a lens insert could be placed. Each endwall temperature resulted from an average of 16 images and, based on an uncertainty analysis, it was determined that five of these 16 averaged images were enough to get a good average. Small positioning crosses were placed on the endwall to identify where each of the 13 images were relative to the turbine vane. An in-house processing routine allowed the 13 images to be assembled into one complete endwall temperature distribution. The infrared camera performed a spatial averaging over 0.37 cm and operated at its maximum viewing area of 21.5 cm by 16 cm represented by 255 by 206 pixels.

The input heat flux was corrected for radiation losses, which amounted to between 7-23 % of the input power, and conduction losses, which amounted to 1.7-3.5 % of the input power. No correction was necessary regarding heat losses from conduction to the turbine vane itself because the vane was constructed using Styrofoam. Using the measured temperatures and the remaining convective heat flux, the heat transfer coefficients were computed and reported as Stanton numbers.

UNCERTAINTY ESTIMATES

The partial derivatives and sequential perturbation methods, described by Moffat (1988), were used to estimate the uncertainties of the measured values. Uncertainties were calculated based on a 95% confidence interval. For each velocity component 15,000 data points were used to compute the mean and turbulence quantities whereas when coincidence data was acquired 20,000 data points were acquired. The estimate of bias and precision uncertainties for the mean velocities were 1% while the precision of the raw velocities was 2.1% for u_{rms} , 1.7% for the v_{rms} and

The El Niño-Southern Oscillation (ENSO) and Pacific subtropical highs (PSHs) affect the livelihoods of people worldwide through their influences on severe natural hazards including tropical storms, coastal erosion, droughts and floods^{1–3}.

EJEMPLO 2: nombre

Several classification methods of circulation weather types have been developed, and are currently used in a wide range of applications (Huth et al., 2008, 2010; Philipp et al., 2010). In addition, in 2002, Sheridan stated that the “Synoptic weather-typing, or the classification of weather conditions or patterns into categories, continues to be popular, and numerous methods have been developed over the past century” (Sheridan, 2002). The increasing interdisciplinary use of circulation weather types in Europe became clear when the European project “Harmonization and Applications of Weather Types Classifications for European Regions—COST733,” where a wide range of classification schemes for different spatial domains were developed and compared within the scope of distinct applications. (Huth et al., 2008, 2010; Philipp et al., 2010).
