Detection : Statistics

The current census of exoplanets

- To date (2023) ~ 5000 confirmed exoplanets.
- This sample has selection biases introduced by the dominant detection techniques.
- Transit favours close orbiting large planets and only edge-on detection.
- Radial Velocity maps massive exoplanets, close-in to the host star.

Detection Statistics Breakdown

Exoplanet Detection at scale

Thesis Goal and Approach:

- Improve the current statistics and remove selection biases.
- Analyze and combine large available astronomical datasets using in Deep Learning.
- Detect exoplanets at scale over the full sky and characterize their physical properties.
- Revise current theories of planet formation in view of the results.

Astrometric Exoplanet Detection

The technique: A companion induces a displacement in the star's position causing it to "wobble" around the system c.o.m.

The challenge: The magnitude of this distortion is so small ($\sim \mu$ as) that so far we only have 2 astrometrically detected exoplanets.

The approach: Apply artificial intelligence to the Gaia catalog for systematic search of companion signature in stars.

Astrometric Signature

Distorsion Magnitude:

$$\alpha = \left(\frac{M_p}{M_*}\right) \left(\frac{a_p}{d}\right) [arcsec]$$

where:

$$\begin{array}{l} M_p = \text{exoplanet mass } [\mathsf{M}_\odot] \\ M_* = \text{host star mass } [\mathsf{M}_\odot] \\ a_p = \text{exoplanet orbit semi-major axis } [\mathsf{AU}] \\ d = \text{distance to the host start } [\mathsf{pc}] \end{array}$$

Figure: (from Author) Astrometric signature α for example (Solar like) exoplanets as a function of distance in pc. The gray dashed line shows the Gaia astrometric precision 100 μas

Use Gaia to detect Exoplanets!

Gaia Mission:

ESA's Gaia mission provides ultra precise ($\sim 100\mu$ as) **all sky** measurements of ($\alpha, \delta, \mu_{\alpha}, \mu_{\delta}, \varpi$) for 1.8 billion sources!.

Total number of sources	# sources in Gaia DR3 1,811,709,771
Number of 5-parameter sources	585,416,709
Number of 6-parameter sources	882,328,109
Number of 2-parameter sources	343,964,953
Sources with mean G magnitude	1,806,254,432
Sources with mean GBP-band photometry	1,542,033,472
Sources with mean GRP-band photometry	1,554,997,939

Figure: Credit : ESA/Gaia/DPAC

2 Astrometry:

4 Project Status: Results and Look-Ahead

Estimations: Gaia should be able to detect ~ 20000 large-mass (1-15 M_J) long period exoplanets ([1]) out to d = 500pc using astrometric exoplanet detection.

Gaia Observations

Credit : ESA/Gaia/DPAC

Astrometric observations:

But Gaia does not measure (α), it measures the 1D displacement ($\Delta \eta$) of the star's position along the scan direction (many times).

Astrometric model (5p):

$$\Delta \eta = [\Delta \alpha^* + \mu_{\alpha^*} t] \sin \theta + [\Delta \delta + \mu_{\delta} t] \cos \theta + \varpi f_{\varpi}$$

Astrometric fit: We can perform a least squares fit to minimize the sum of squared residuals :

$$R_i = \Delta \eta_i^{observed} - \Delta \eta_i^{computed}$$

Statistics and imitations

2 Astrometry: Technique and Gaia data

3 Artificial Intelligence: Approach and Application

4 Project Status: Results and Look-Ahead

Artificial Intelligence

Basic hypothesis: The presence of companion should reflect in the astrometric fit quality. We can use fit quality statistics to induce the presence of a companion.

$$\chi^2 = \frac{1}{\nu} \sum_{i=1}^{N} \frac{R_i^2}{\sigma_i^2}$$

where:

 $\begin{aligned} R_i &= \Delta \eta_i \text{ Residuals} \\ \sigma_i &= \Delta \eta_i \text{ measurement uncertainty} \\ \nu &= \mathsf{N}_{obs} - \mathsf{5} \end{aligned}$

Methodology: Generate deep learning models capable of predicting the probability of a star in the Gaia catalog to hold a substellar companion.

Figure: (from Author) Illustrative Deep Neural Network Architecture showing the weights of each neuron.

3 Artificial Intelligence: Approach and Application

4 Project Status: Results and Look-Ahead

Artificial Intelligence : Supervised Learning

Approach: Use a labeled dataset to train neural networks.

Attributes (Fit statistics)

```
x_1 = ruwe

x_2 = astrometric\_chi2\_al

x_3 = astrometric\_excess\_noise

x_n = ...
```

Labels

$$\label{eq:comparison} \begin{split} 1 &= \mathsf{star} \text{ with Gaia detectable companion} \\ 0 &= \mathsf{star} \text{ with NO Gaia detectable companion} \end{split}$$

Output:

$$p_0(\bar{x}) = P(c = 0 | x_1, x_2, ..., x_n)$$

$$p_1(\bar{x}) = P(c = 1 | x_1, x_2, ..., x_n)$$

But ... No negative labels!: There is no catalog of stars with *NO* companion.

Generate synthetic data: We simulate 1D Gaia-like observations for sources with and without a companion and perform a least-squares fit.

Figure: (from Author) Simulated Gaia-like observations.

AI Model : Architectures and Metrics

Deep Learning Architectures:

We use deterministic and probabilistic neural network architecture.

- 1. (Deterministic) Deep Neural Network architecture for companion detection.
- 2. (Probabilistic) Deep probabilistic Neural Network for orbital parameters characterisation.

The later to incorporate the ability to estimate the uncertainty on orbital parameter estimation. Quality Metrics: Classification metrics:

- 1. F1-score
- 2. Log Loss

$$F1 = \frac{2 * Precision * Recall}{Precision + Recall} = \frac{2 * TP}{2 * TP + FP + FN}$$
$$L = \frac{1}{N} \sum_{i=1}^{N-1} y_i \cdot \log(p_i) + (1 - y_i) \cdot \log(1 - p_i)$$

F1-score: trade-off between precision and recall. In this domain it is important that we correctly classify stars that do host exoplanets as such (precision), and that we capture as many of those as possible (recall).

Look-Ahead: Planned Activities

Planned work - short term:

- Improve external calibration e.g. using further Gaia Non Single-Stars results
- 2. Improve **external calibration** to extend the coverage of the Mass-Period parameter space.
- 3. Apply AI model to unseen data from the Gaia DR3 catalog.

Planned work - long term:

- 1. Propose follow up observations on candidate exoplanet list.
- 2. Work on orbital parameter $(i, e, a, \Omega, \omega, \nu)$ recovery with Bayesian Neural Networks.
- Incorporation other data types (radial velocity) for binary parameters (mass) contraining.
